Djomou Bernice**

# Problem Statement

- Malnutrition continues to be a major public health challenge in Africa.
- This occurs in regions affected by food insecurity, poverty, and limited access to healthcare.
- However, current early-detection systems remain insufficient.
- This project seeks to address these gaps by leveraging community-level data to identify vulnerable children early and enable timely, targeted interventions.

# Project Objectives

- Identify key socioeconomic, dietary, and environmental factors contributing to malnutrition risk.
- To evaluate the patterns of malnutrition in the study area
- Empower healthcare workers with interpretable, data-backed insights for early identification and intervention.
- To recommend target intervention based on analytical findings.

# Methodology

## Data Cleaning

Original dataset structure

- 235957 rows and 21 columns
- 42 duplicates rows (Deleted)
- Missing values (frequency of Meals column)
- Spelling inconsistencies (corrected)
- Columns with high range of numerical values were grouped.

## Tools used

- Excel
- Power BI.

# Background

Three key anthropometric indicators are used to assess the nutritional status of children under five.

Measurement	What it Detects	Type of Malnutrition
<b>Weight-for-Age</b>	Light for age	Underweight (general malnutrition)
<b>Height-for-Age</b>	Short for age	Stunting (long-term malnutrition)
<b>Weight-for-Height</b>	Too thin for height	Wasting (short-term malnutrition)

# WHO Z-Score Classification

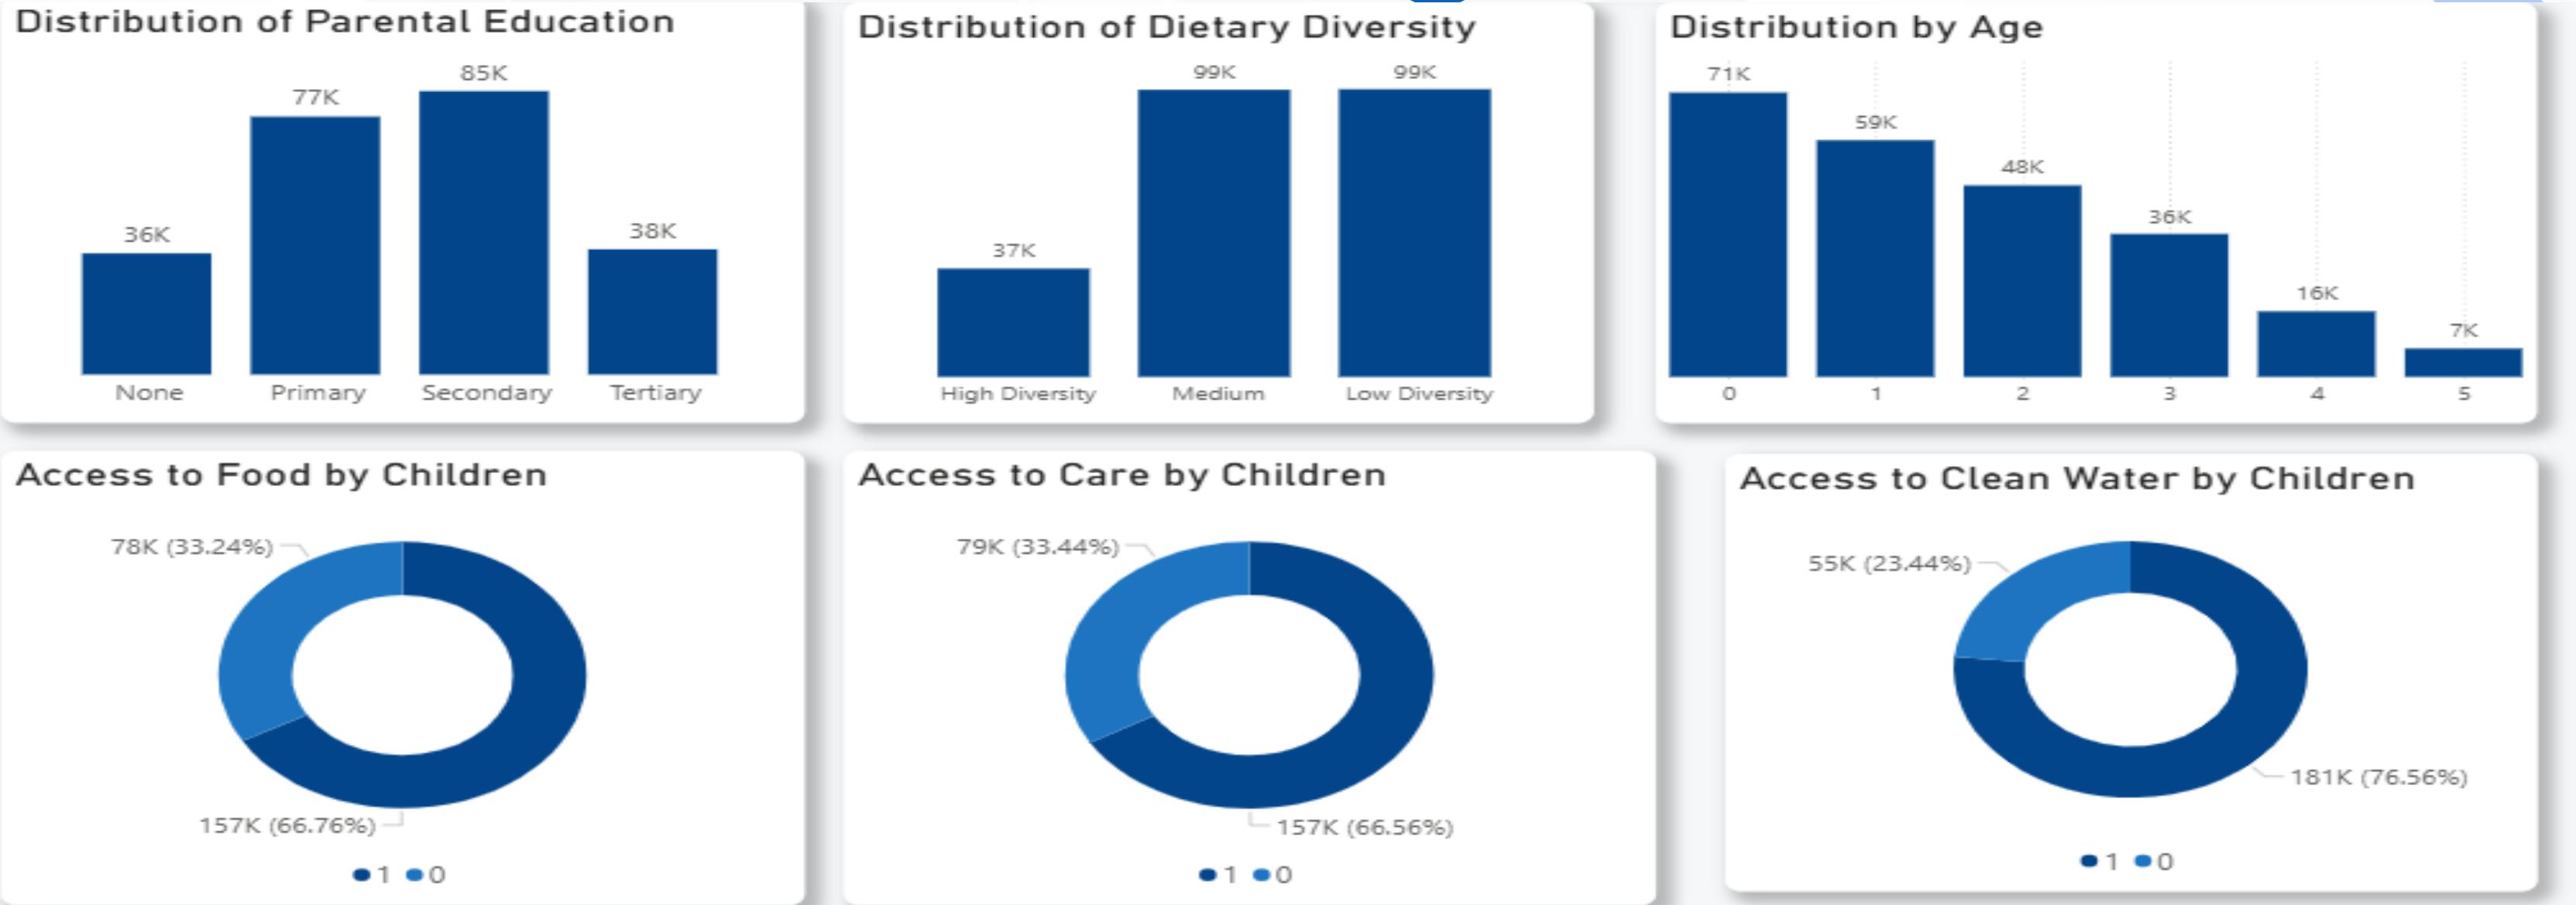

Z-score value	Category	Meaning
$Z > 2$	<b>Overweight</b>	Child is above expected growth
$2 \leq Z \geq -2$	<b>Normal</b>	Child is within healthy growth range
$-3 \leq Z < -2$	<b>Moderately malnourished</b>	Child is below expected growth
$Z < -3$	<b>Severely malnourished</b>	Child is far below healthy range; high risk

# Data Insights

- Total children: 235915
- Average Weight-for-Age: -1.30
- Average Height-for-Age: -1.30
- Average Weight-for-Height: -0.87
- High malnutrition risk %: 26.7%
- Moderate malnutrition risk %: 33.3%
- Low malnutrition risk %: 40.0%

# Data Insight

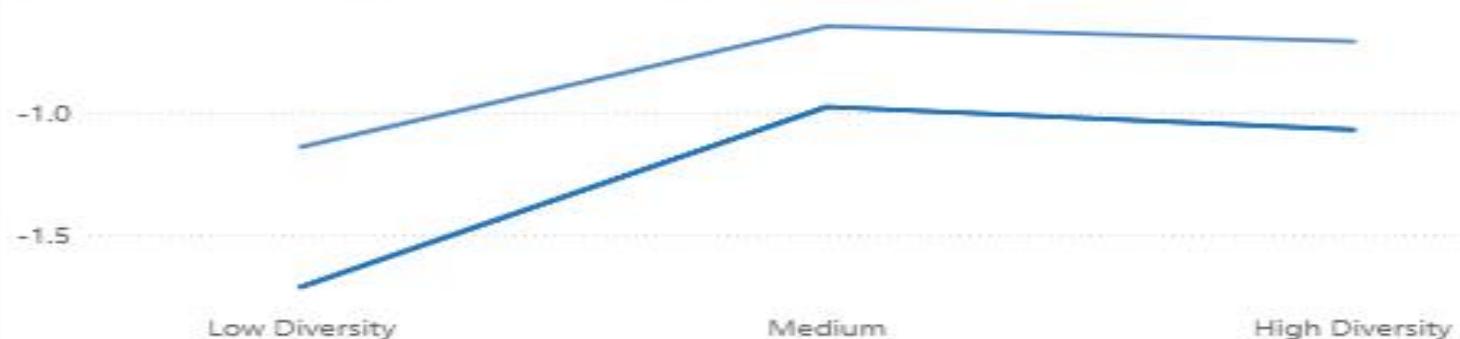

- Majority of children have parents with primary and secondary education, only a few have tertiary education (about 16%).
- Just a few (approx. 16%) have high dietary diversity (eat more than 6 types of meals).
- Most of the children (around 71K) are under 1 year.
- More than 30% of children have no access to food and healthcare.

# Data Insight

Nutritional Status by Dietary Diversity

● Avg Weight-for-Age ● Avg Height-for-Age ● Avg Weight-for-Height

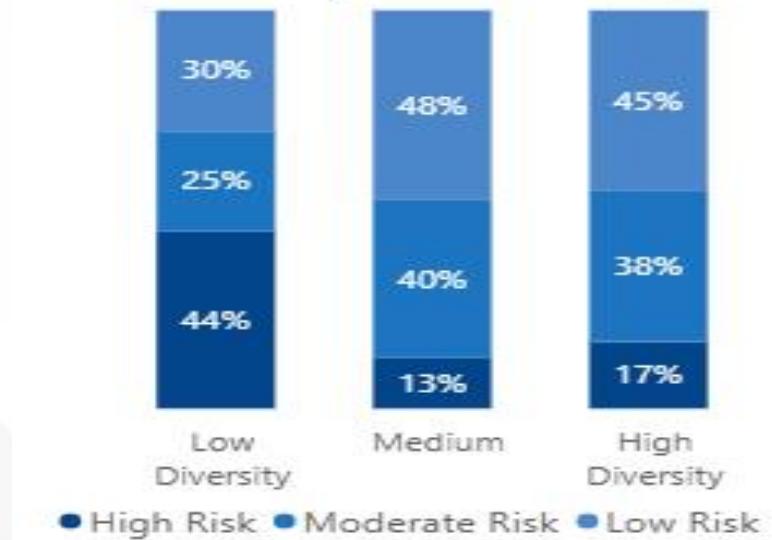

Nutritional Status by Parental Education

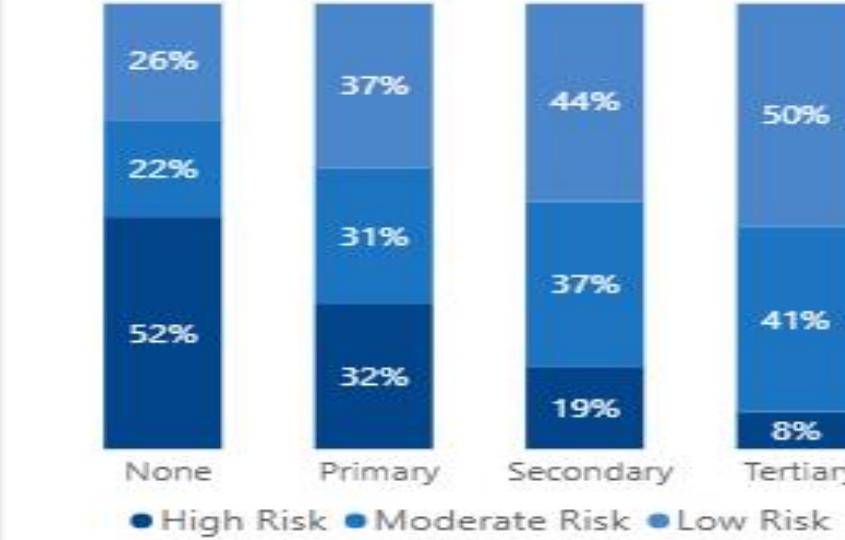

● Avg Weight-for-Age ● Avg Height-for-Age ● Avg Weight-for-Height

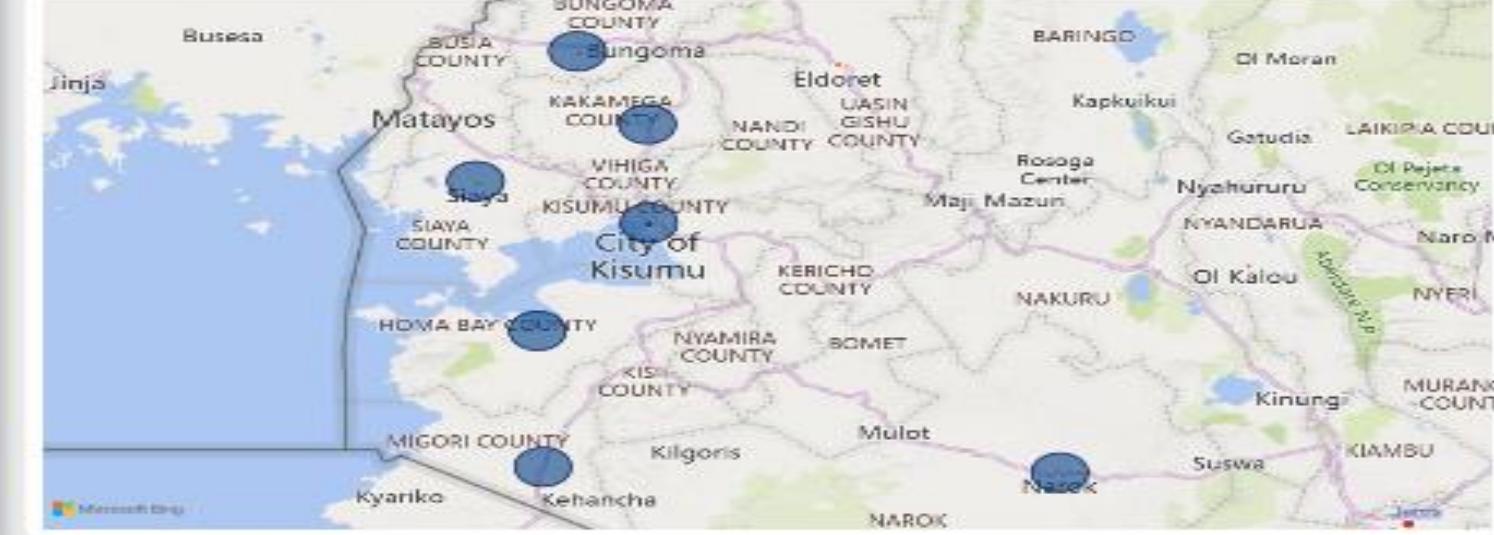

Risk Level by Diet Diversity

Risk Level by Parental Education

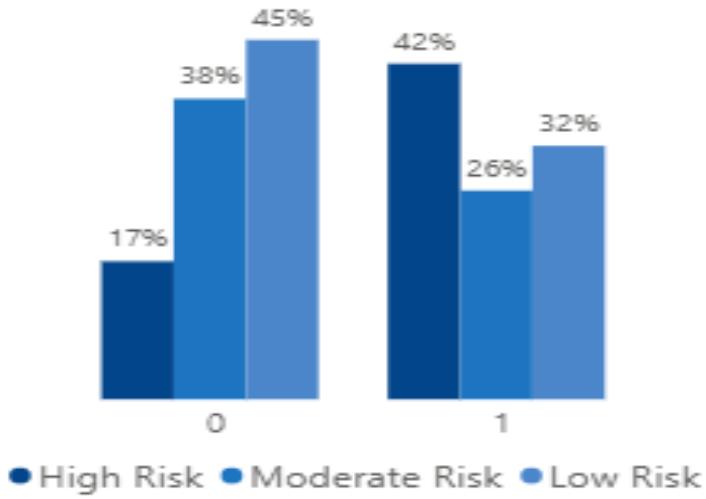

High Risk % by Location

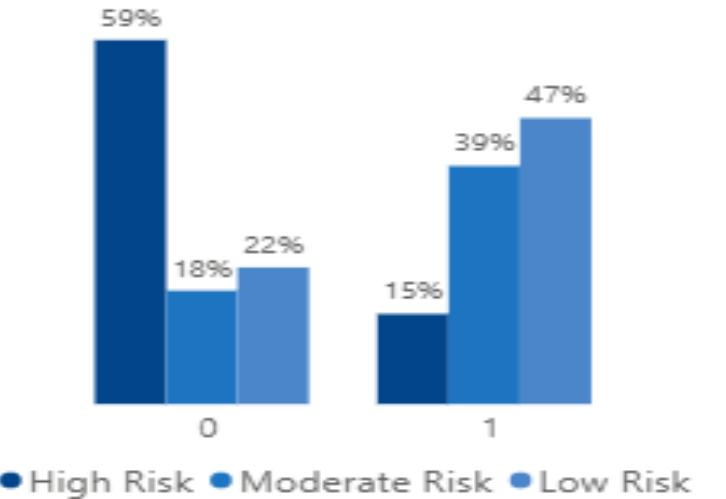

- Children with low diversity have low z-scores of -1.7 for WFA and HFA. This is close to underweight and stunting.
- As parent education decreases, malnutrition worsens.
- Poor parental education and dietary diversity correlate with high malnutrition risk.
- The even bubble size in the map shows that the proportion of children with high-risk malnutrition in all location are similar (about 26%).

# Data Insight

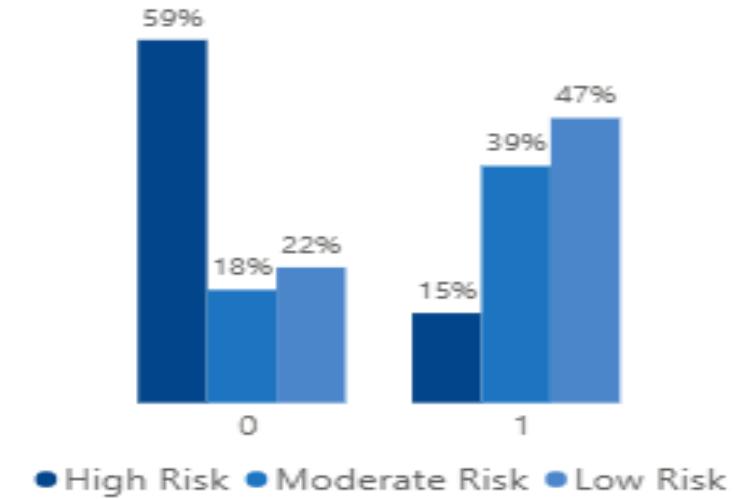

Risk Level by Seasonal Variation

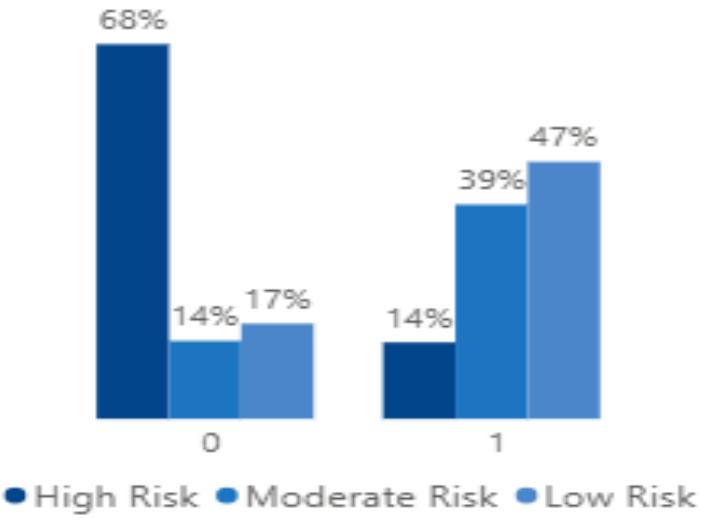

Risk Level by Sanitation Facilities

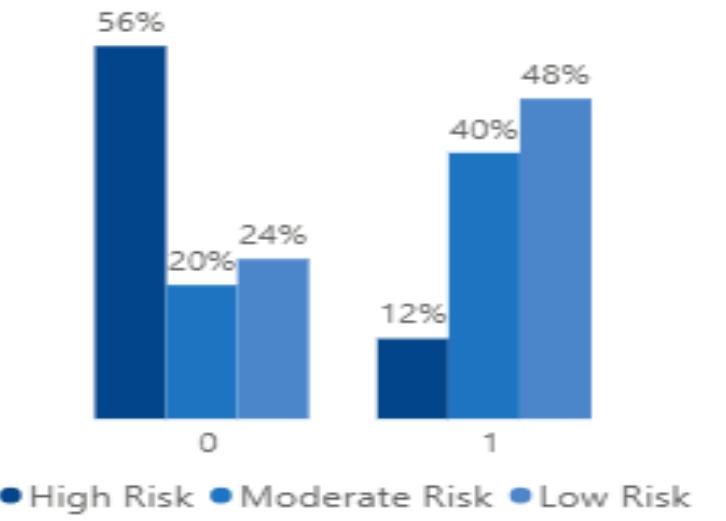

Risk Level by Market Access

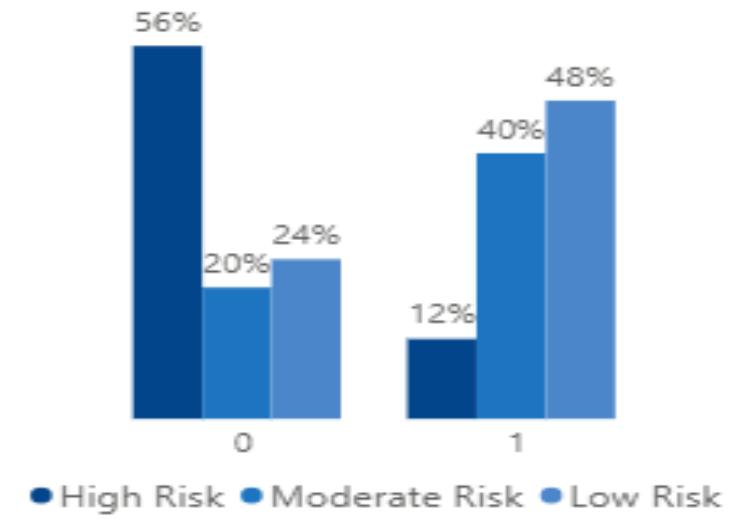

Risk Level by Clean Water Access

Risk Level by Access to care

Risk Level by Food Availability

- Poor sanitation, poor market access, lack of clean water, lack of access to care and poor food availability shows high percentage of high-risk children
- However, high-risk increases when there is seasonal variations, as this can affect food availability and disease patterns.

# Recommendation

- Improve dietary diversity through nutrition programs.
- Educate parents on healthy nutrition.
- Enhance food availability and market access.
- Improve Water, Sanitation and Hygiene (WASH) infrastructure.
- Strengthen access to healthcare services.
- Implement seasonal preparedness strategies.

# Implementation Plan

Action	Timeline	Resources Required	Key Stakeholders
Launch community nutrition education campaigns. Integrate nutrition education into antenatal and postnatal clinics.	1-3 months	Training materials, community health educators.	NGOs, community health workers, Ministry of Health, hospitals, PHCs, midwives
Enhance food availability and market access. Support local farmers.	6-12 months	Seed, fertilizers	Governments, farmers
Improve Water, Sanitation and Hygiene (WASH) infrastructure. Build and upgraded water and sanitation facilities.	6-18 months	Construction materials, engineers	Governments
Strengthen access to healthcare services. Expand growth monitoring services.	1-6 months	CHWs, Nurses, equipment (scales)	Governments, hospital, health workers, UNICEF
Implement seasonal preparedness strategies. Identify high-risk seasons and provide food and support.	Annually	Food, cash	NGOs, Government

# Conclusion

- Malnutrition remains a critical public health challenge, particularly among children under five in low-resource settings.
- The analysis shows that malnutrition risk is influenced by poor education, poor dietary diversity, and limited access to healthcare, clean water, and sanitation facilities.
- Z-score indicators consistently show poorer outcomes among children from households with constrained resources and reduced food availability.
- To address these gaps, strengthening community-based nutrition education help caregivers make informed decisions.
- Improving access to clean water, sanitation facilities, and primary healthcare services is essential to reducing disease burden and supporting growth.
- Finally, interventions should account for seasonal food shortages by implementing year-round food support systems, improved market access, and nutrition-sensitive agricultural programs.
